2. **Introduction**

   The SMTL were requested by the client to perform various physical tests on Allevyn AG Adhesive Foam Wound Dressings.

   This testing was originally reported in SMTL Test Report 09/3104/1.

3. **Test Product(s)/Sample(s)**

   **TABLE 1.** Test Product(s)/Sample(s) tested by SMTL.

3.1 Departures/Abnormalities of Sample Condition
None

4. Date of Testing
August-November 2009

5. Testing Details
5.1 Moisture Vapour Transmission Rate
The moisture vapour permeability of the dressings was determined using SMTL test method TM-8.\(^1\)

In this test, a sample of dressing is applied to a Paddington cup to which is added 20 ml of a solution of sodium and calcium chloride containing 142 mmole/litre of sodium ions and 2.5 mmole/litre of calcium ions.

The cup is placed in an inverted position (with the test solution in contact with the sample) upon the pan of a top loading balance located within an incubator set at 37\(\pm 2\)\(^\circ\)C. The balance is connected to an electronic data logging device which records changes in the weight of the cup resulting from the loss of moisture vapour through the dressing. A tray containing 1 kg of freshly dried silica gel is placed in the bottom of the incubator to maintain a low relative humidity within the chamber.

At the end of the test the recorded data is down-loaded for examination.

5.2 Fluid Handling Properties
The fluid handling properties of the dressings were examined using SMTL test method TM-390,\(^2\) which is written in accordance with the European Standard BS EN 13726:1:2002 - Test methods for primary wound dressings. Part 1: Aspects of absorbency. Section 3.3 - Fluid Handling Capacity (absorbency plus moisture vapour transmission rate, liquid in contact).\(^3\)

In this test, five samples of each dressing are applied to Paddington cups, to which are added 20 ml of a solution of sodium/calcium chloride containing 142 mmole/litre of sodium ions and 2.5 mmole/litre of calcium ions. The cups are weighed using a calibrated analytical balance and placed in a temperature and humidity controlled incubator used to maintain an environment of 37\(\pm 2\)\(^\circ\)C and a relative humidity level below 20\% for a period of 24 hours.

At the end of the test the cups are removed from the incubator, and are allowed to equilibrate at room temperature for a period of 30 minutes prior to reweighing on the analytical balance.

From these weighings the loss in weight due to the passage of moisture vapour through the dressing is determined. The base of each cup is then removed and any remaining fluid allowed to drain.\(\dagger\) After a period of 15\(\pm2\)min the cup is then reweighed once again.
and the weight of fluid retained by the dressing calculated by difference. This test can be repeated over a period of 48 hours.

5.3 Conformability

The conformability of the dressing was determined using SMTL test method TM-16.\(^4\)

The testing apparatus is a modification of the Apparatus for the Measurement of Waterproofness as originally described in the British Pharmacopoeia 1988, Appendix XX K and recently adopted as a European Standard BS EN 13726-3: 2003 - Test methods for primary wound dressings: Waterproofness. It consists of a chamber, open at one end, bearing a flange with an internal diameter of 50 mm. A retaining ring with the same internal diameter as the hole in the flange is mounted over the open end of the cylinder and this can be lowered down and clamped onto the flange, by means of a screw thread.

In use, a sample of the dressing under examination is placed on the flange and held firmly in place by means of the retaining ring.

During the course of this test, air is slowly forced into the chamber by means of a large syringe. The resultant rise in the pressure within the chamber causes the dressing to expand and form a hemisphere which gradually increases in size.

The pressure in the chamber, measured by means of a transducer and digital display unit, is increased until the upper surface of the dressing comes into contact with a marker placed 20 mm above the surface of the dressing at the start of the test. This pressure value is then recorded.

In this test, the conformability of a dressing is considered to be inversely proportional to the pressure required to distort it by a predetermined amount.

5.4 Waterproofness

The waterproofness of the outer layer of the dressing was determined using SMTL test method TM-395,\(^5\) which is written in accordance with the European Standard BS EN 13726:3:2003 - Section 3.2.\(^6\)

In this test, a specimen is cut from the dressing under test that is sufficient to completely cover the opening of the test cell (the test cell is a modified Paddington Cup as illustrated in Figure 1 of BS EN 13726:3:2003). The test cell is then filled completely with water at 21±2°C. The specimen is then slid horizontally over the cell with its outer facing layer in contact with the water in such a way as to avoid the inclusion of air between the surface of the water and the lower surface of the specimen.

The upper surface is then covered with a dry filter paper and the upper ring of the apparatus tightened. A hydrostatic head of 500mm is then generated and maintained for 300±10sec, after which time the filter paper is examined for penetration of water and

\(\dagger\) If there is an accumulation of test fluid between two components of the dressing, the inner component must be slit with a scalpel blade to allow free drainage of the entrapped fluid.

---

\(^4\) The information contained in this report is proprietary, and is not for circulation without the consent of the Surgical Material Testing Laboratory (S.M.T.L.), or the commissioning authority/company. This report shall not be reproduced except in full without the written approval of S.M.T.L., Princess of Wales Hospital, Colly Road, Bridgend, CF31 1RG.

the results recorded. The test is performed on three individual specimens, and if water penetration has occurred on any of the three specimens then the sample is deemed to have failed the test.

5.5 List of SMTL Test Methods Used.
- TM-8 - Moisture Vapour Transmission Rate from Dressings by Electronic Data Capture Method\(^1\)
- TM-390 - Fluid Handling Capacity BS EN 13726-1:2002\(^2\)
- TM-16 - Conformability of Hydrocolloid and Film Dressings\(^4\)
- TM-395 - Waterproofness to BS EN 13726-3:2003\(^5\)

5.6 Standards relevant to the test method.
- The test method TM-390 Fluid Handling Capacity BS EN 13726-1:2002\(^2\) is performed in accordance with the method described in the European Standard BS EN 13726-1:2002: Test methods for primary wound dressings. Aspects of absorbency. Section 3.3 Fluid handling capacity (absorbency plus moisture vapour transmission rate, liquid in contact)\(^3\)
- The SMTL test method TM-395\(^5\) is written in accordance with the method described in the BS EN 13726-3: 2003: Non-active medical devices - Test methods for primary wound dressings - Part 3: Waterproofness

5.7 Deviations/exclusions from, and additions to standard methods.
- Due to the high fluid handling capacity expected with at least one of the dressings, the fluid amount introduced into the Paddington cups at the start of the testing was increased from 20ml to 30ml for all testing.
- BS EN 13726-3:2003 waterproofness has a stated non-penetration time of 5 minutes for compliance, the dressings were tested over 5 minutes as per the standard and also over an extended period of 15 minutes at the clients request.

5.8 Sampling Details
All samples were selected and supplied by the client.

5.9 Sample Preparation
As per the relevant SMTL Test Method.
6. Results

6.1 Moisture Vapour Transmission Rate (MVTR)

Results from MVTR experiments are presented in Tables 2 and 3. Data is also expressed graphically in Figures 1 and 2.
